Problem 1: Consider the integral function

$$J[y] = \int_1^2 \frac{y'(x)^2}{x} dx$$

The integrand here is strongly convex (on an appropriately defined set). Find the unique $y \in D$ that minimizes $J[y]$ over D , for the following cases. In each case, is the minimizer (if it exists) unique?

Part (a) $D = \{y \in C^1[1, 2] : y(1) = 0, y(2) = 3\}$

Solution

If J is a minimum at $y \in D$ then y must satisfy the Euler-Lagrange equation $F_y(x, y, y') - \frac{d}{dx} F_{y'}(x, y, y') = 0$ where $F(x, y, y') = \frac{y'(x)^2}{x}$.

$$\begin{aligned} \frac{\partial F}{\partial y} - \frac{d}{dx} \frac{\partial F}{\partial y'} &= 0 \implies \frac{\partial F}{\partial y} = \frac{d}{dx} \frac{\partial F}{\partial y'} \\ \implies 0 &= \frac{d}{dx} \frac{2y'}{x} \implies \int 0 dx = \int \frac{d}{dx} \frac{2y'}{x} dx \\ \implies \frac{2y'}{x} &= C \quad (C \in \mathbb{R}) \\ \implies y' &= Bx \quad (B \in \mathbb{R}) \\ \implies \int y' dx &= \int Bx dx \\ \implies y &= c_1 x^2 + c_2 \quad (c_1, c_2 \in \mathbb{R}) \end{aligned}$$

y must also satisfy the boundary conditions:

$$\begin{cases} y(1) = c_1 + c_2 = 0 \\ y(2) = 4c_1 + c_2 = 3 \end{cases} \implies c_1 = \frac{3}{5}, c_2 = -\frac{3}{5} \implies \boxed{y = \frac{3}{5}x^2 - \frac{3}{5}}$$

We have shown with Euler-Lagrange equation the necessary conditions for y to minimize $J[y]$ and because we are given the integrand is strongly convex on the defined set D , we have the sufficient conditions to guarantee y is the unique minimizer.

Part (b) $D = \{y \in C^1[1, 2] : y(2) = 3\}$

Solution

From the notes given in class, we have the following:

Theorem. If $F(x, y, y')$ is strongly convex in (y, y') then a solution $y(x)$ of the Differential Euler-Lagrange equation uniquely minimizes

$$J[y] = \int_a^b F(x, y, y') dx$$

over $\{y \in C'[a, b] : y(b) = B\}$ if $F_{y'}(a, y(a), y'(a)) = 0$.

We find the solution to the Euler-Lagrange equation $F_y(x, y, y') - \frac{d}{dx} F_{y'}(x, y, y') = 0$ where $F(x, y, y') = \frac{y'(x)^2}{x}$.

$$\begin{aligned} \frac{\partial F}{\partial y} - \frac{d}{dx} \frac{\partial F}{\partial y'} &= 0 \implies \frac{\partial F}{\partial y} = \frac{d}{dx} \frac{\partial F}{\partial y'} \\ \implies 0 &= \frac{d}{dx} \frac{2y'}{x} \implies \int 0 dx = \int \frac{d}{dx} \frac{2y'}{x} dx \\ \implies \frac{2y'}{x} &= C \quad (C \in \mathbb{R}) \\ \implies y' &= Bx \quad (B \in \mathbb{R}) \\ \implies \int y' dx &= \int Bx dx \\ \implies y &= c_1 x^2 + c_2 \quad (c_1, c_2 \in \mathbb{R}) \end{aligned}$$

y must also satisfy the boundary condition:

$$\begin{aligned} y(2) = 4c_1 + c_2 &= 3 \implies c_2 = 3 - 4c_1 \\ \implies y &= c_1 x^2 + (3 - 4c_1) \\ \implies y &= c_1(x^2 - 4) + 3 \end{aligned}$$

thus

$$\begin{aligned} F_{y'}(1, y(1), y'(1)) &= 0 \implies \frac{2y'(1)}{1} = 0 \\ \implies y'(1) &= 0 \\ \implies 2c_1(1) & \\ \implies c_1 &= 0 \end{aligned}$$

which implies

$$\boxed{y(x) = 3}$$

Given the integrand is strongly convex on the defined set D along with the theorem mentioned above, y uniquely minimizes $J[y]$ over D .

Part (c) $D = C^1[1, 2]$

Solution

If J is a minimum at $y \in D$ then y must satisfy the Euler-Lagrange equation

$F_y(x, y, y') - \frac{d}{dx} F_{y'}(x, y, y') = 0$ where $F(x, y, y') = \frac{y'(x)^2}{x}$.

$$\begin{aligned} \frac{\partial F}{\partial y} - \frac{d}{dx} \frac{\partial F}{\partial y'} &= 0 \implies \frac{\partial F}{\partial y} = \frac{d}{dx} \frac{\partial F}{\partial y'} \\ \implies 0 &= \frac{d}{dx} \frac{2y'}{x} \implies \int 0 dx = \int \frac{d}{dx} \frac{2y'}{x} dx \\ \implies \frac{2y'}{x} &= C \quad (C \in \mathbb{R}) \\ \implies y' &= Bx \quad (B \in \mathbb{R}) \\ \implies \int y' dx &= \int Bx dx \\ \implies y &= c_1 x^2 + c_2 \quad (c_1, c_2 \in \mathbb{R}) \end{aligned}$$

From strong convexity and observation we see if $y = c_2$, we achieve a minimum for $J[y] = \int_1^2 \frac{y'(x)^2}{x} dx$ since $y'(x)^2 \geq 0$ and $x \in [1, 2]$ which implies $J[y] \geq 0$. However y is not a unique minimizer since $c_2 \in \mathbb{R}$.

Problem 2: Let $\delta(x)$ be the Dirac delta function. Justify the identity

$$\delta(1 - x^2) = \frac{\delta(x - 1) + \delta(x + 1)}{2}$$

Hint: consider the integral $\int_{-\infty}^{\infty} \delta(1 - x^2) dx$

Solution For any continuous function $f(x)$, we have

$$\int_{-\infty}^{\infty} f(x) \delta(1 - x^2) dx = \underbrace{\int_0^{\infty} f(x) \delta(1 - x^2) dx}_{(1)} + \underbrace{\int_{-\infty}^0 f(x) \delta(1 - x^2) dx}_{(2)}$$

If we let $\sqrt{u} = x$ and $\frac{1}{2\sqrt{u}} du = dx$

$$(1) = \int_0^{\infty} \frac{f(\sqrt{u}) \delta(1 - u)}{2\sqrt{u}} du = \frac{f(1)}{2}$$

If we let $-\sqrt{u} = x$ and $-\frac{1}{2\sqrt{u}} du = dx$

$$(2) = - \int_{-\infty}^0 \frac{f(-\sqrt{u}) \delta(1 - u)}{2\sqrt{u}} du = \int_0^{\infty} \frac{f(-\sqrt{u}) \delta(1 - u)}{2\sqrt{u}} du = \frac{f(-1)}{2}$$

thus

$$\begin{aligned} \int_{-\infty}^{\infty} f(x) \delta(1 - x^2) dx &= \frac{1}{2} [f(1) + f(-1)] \\ &= \frac{1}{2} \left[\int_{-\infty}^{\infty} f(x) \delta(x - 1) dx + \int_{-\infty}^{\infty} f(x) \delta(x + 1) dx \right] \\ &= \frac{1}{2} \int_{-\infty}^{\infty} f(x) (\delta(x - 1) + \delta(x + 1)) dx \\ &= \int_{-\infty}^{\infty} f(x) \frac{\delta(x - 1) + \delta(x + 1)}{2} dx \end{aligned}$$

Since δ functions are defined only by how they behave in integrals we conclude

$$\boxed{\delta(1 - x^2) = \frac{\delta(x - 1) + \delta(x + 1)}{2}}$$

Problem 3: Let $f : [0, 1] \rightarrow \mathbb{R}$ be a given continuous function and consider the following differential equation for the function y :

$$\begin{cases} y'''(x) = f(x) & 0 \leq x \leq 1 \\ y(0) = y'(0) = y''(0) = 0 \end{cases} \quad (1)$$

Intuitively, finding $y(x)$ requires three integrations. This problem illustrates that by employing a Green's function we can actually find y via a *single* integral.

Part (a) Show that if the Green's function $u = G(x; s)$ satisfies

$$\begin{cases} u'''(x) = \delta(x - s) & 0 \leq x \leq 1 \\ u(0) = u'(0) = u''(0) = 0 \end{cases}$$

then the function

$$y(x) = \int_0^1 f(s)G(x; s)ds \quad (2)$$

satisfies (1).

Solution

From the notes given in class, we have the following:

Theorem.

The function $y(x) = \int_0^1 f(s)G(x; s)ds$ satisfies the differential equation

$$\begin{cases} L[y] = y'''(x) = f(x) & 0 \leq x \leq 1 \\ y(0) = y'(0) = y''(0) = 0 \end{cases}$$

Let us first observe

$$\begin{aligned} L[y] = y''' &= \frac{d^3}{dx^3} \left(\int_0^1 f(s)G(x; s)ds \right) \\ &= \int_0^1 \frac{d^3}{dx^3} (f(s)G(x; s))ds \\ &= \int_0^1 f(s) \frac{d^3}{dx^3} (G(x; s))ds \\ &= \int_0^1 f(s)G'''(x; s)ds \\ &= \int_0^1 f(s)L[G]ds \end{aligned}$$

and

$$L[G] = G'''(x; s) = \delta(x - s), \quad 0 \leq x \leq 1$$

thus

$$\begin{aligned}
L[y] &= L \left[\int_0^1 f(s) G(x; s) ds \right] \\
&= \int_0^1 L \left[f(s) G(x; s) \right] ds \\
&= \int_0^1 f(s) L[G] ds \\
&= \int_0^1 f(s) \delta(x - s) ds \\
&= f(x)
\end{aligned}$$

along with the boundary conditions given $G(0; s) = 0$

$$\begin{aligned}
y(0) &= \int_0^1 f(s) \underbrace{G(0; s)}_0 ds = 0 \\
y'(0) &= \int_0^1 f'(s) \underbrace{G(0; s)}_0 ds = 0 \\
y''(0) &= \int_0^1 f''(s) \underbrace{G(0; s)}_0 ds = 0
\end{aligned}$$

We have showed (2) satisfies (1).

Part (b) Find the Green's function $G(x : s)$ for this problem

$$\begin{cases} y'''(x) = f(x) & 0 \leq x \leq 1 \\ y(0) = y'(0) = y''(0) = 0 \end{cases}$$

Solution To find Green's function we solve for

$$\begin{cases} u'''(x) = \delta(x - s) & 0 \leq x \leq 1 \\ u(0) = u'(0) = u''(0) = 0 \end{cases}$$

where $u(x) = G(x; s)$.

For $x \neq s$ the differential equation is

$$u'''(x) = 0 \quad 0 \leq x \leq 1$$

whose general solution is found to be

$$u(x) = Ax^2 + Bx + C \quad (A, B, C \in \mathbb{R})$$

thus

$$u(x) = \begin{cases} Ax^2 + Bx + C & x < s \\ Ex^2 + Dx + F & x > s \end{cases}$$

The boundary conditions require

$$\begin{aligned} u(0) = 0 & \implies Ax^2 + Bx + C = 0 \implies C = 0 \\ u'(0) = 0 & \implies 2Ax + B = 0 \implies B = 0 \\ u''(0) = 0 & \implies 2A = 0 \implies A = 0. \end{aligned}$$

The Green function now has the form

$$u(x) = \begin{cases} 0 & x < s \\ Ex^2 + Dx + F & x > s. \end{cases}$$

We also need to satisfy the second derivative discontinuity condition since

$$u''' = \delta(x - s) \Rightarrow u'' = H(x - s)$$

$$\begin{aligned} u''(s^+) - u''(s^-) = 1 & \implies 2E - 0 = 1 \\ & \implies 2E = 1 \\ & \implies E = \frac{1}{2} \end{aligned}$$

The Green function now has the form

$$u(x) = \begin{cases} 0 & x < s \\ \frac{1}{2}x^2 + Dx + F & x > s. \end{cases}$$

Together with the need to satisfy the first derivative continuity condition since $u' = \int H(x-s)dx$ is continuous.

$$\begin{aligned} u'(s^+) = u''(s^-) &\implies s + D = 0 \\ &\implies D = -s \end{aligned}$$

The Green function now has the form

$$u(x) = \begin{cases} 0 & x < s \\ \frac{1}{2}x^2 - sx + F & x > s. \end{cases}$$

Along with the continuity condition of u since u' is continuous which implies u is continuous.

$$\begin{aligned} u(s^+) = u(s^-) &\implies \frac{1}{2}s^2 - s^2 + F = 0 \\ &\implies \end{aligned}$$
